## Background

Across the regulatory frameworks (REACH, Biocidal Products Regulation (BPR), Plant Protection Products Regulation (PPPR), and regulations concerning human and veterinary medicinal products), the regulatory landscape shows consistent reliance on fish bioaccumulation testing despite the availability of validated non-vertebrate and in vitro approaches. This reveals lack of certainty among the regulatory community and industry about applicability domains, advantages and disadvantages of the available New Approach Methodologies (NAMs). Also, there are vast differences among the EU chemical regulations in data requirements and the possibility to use other/additional data for hazard or risk assessment in a Weight of Evidence approach (WoE).

Thus, the German Environment Agency had initiated a project to develop an *Integrated Assessment Strategy for Aquatic and Terrestrial Bioaccumulation* (Figure 1) and to evaluate whether the NAMs for aquatic bioaccumulation assessment are fit for use in regulatory decision making.

## Test systems

Test data for 26 substances were collected and compared: Fish in vivo, fish in vitro and *Hyalella azteca* in vivo BCFs. Existing test data as well as tests performed within the project were used (Table 1).

The usability of the rat depletion assay to evaluate the bioaccumulation potential in air breathers for some substances was evaluated.

## Lessons learned

NAMs are well suited for reliably assessing bioaccumulation potential within their domain of applicability, thus reducing need for vertebrate testing. Nonetheless, the data also show the importance of critical evaluation of all test results, expert judgement, and the need to consider all available data in a WoE evaluation.

**Variability:** Physico-chemical data (e.g.  $\log K_{OW}$ ), which decide whether a substance needs a B-assessment, can vary *substantially* (cf. poster 3.01.P-Mo143).

**Fish in vitro (OECD TG 319 A/B):** If no biotransformation can be determined in a substrate depletion assay, it may be unclear if the substance does not biotransform or if the assay conditions were not suitable for the test substance. Also, the IVIVE BCF is solely based on the IVIVE model, its parameterisation and the substance-specific input data (e.g.  $\log K_{OW}$ ).

Table 1: Data set of the 26 chemicals

Substance name	CAS	Water breathing organisms						Air breathing organisms
		Tier 1	Tier 2	Tier 3		Tier 4		
		Consolidated $\log K_{OW}$	Consolidated $\log K_{OA}$	Mean fish QSAR BCF	IVIVE BCF	HYBIT BCF	Experimental fish BCF range	IVIVE BMF (rat)
Simazine	122-34-9	2.12	8.94	10	7	9	1 - 214

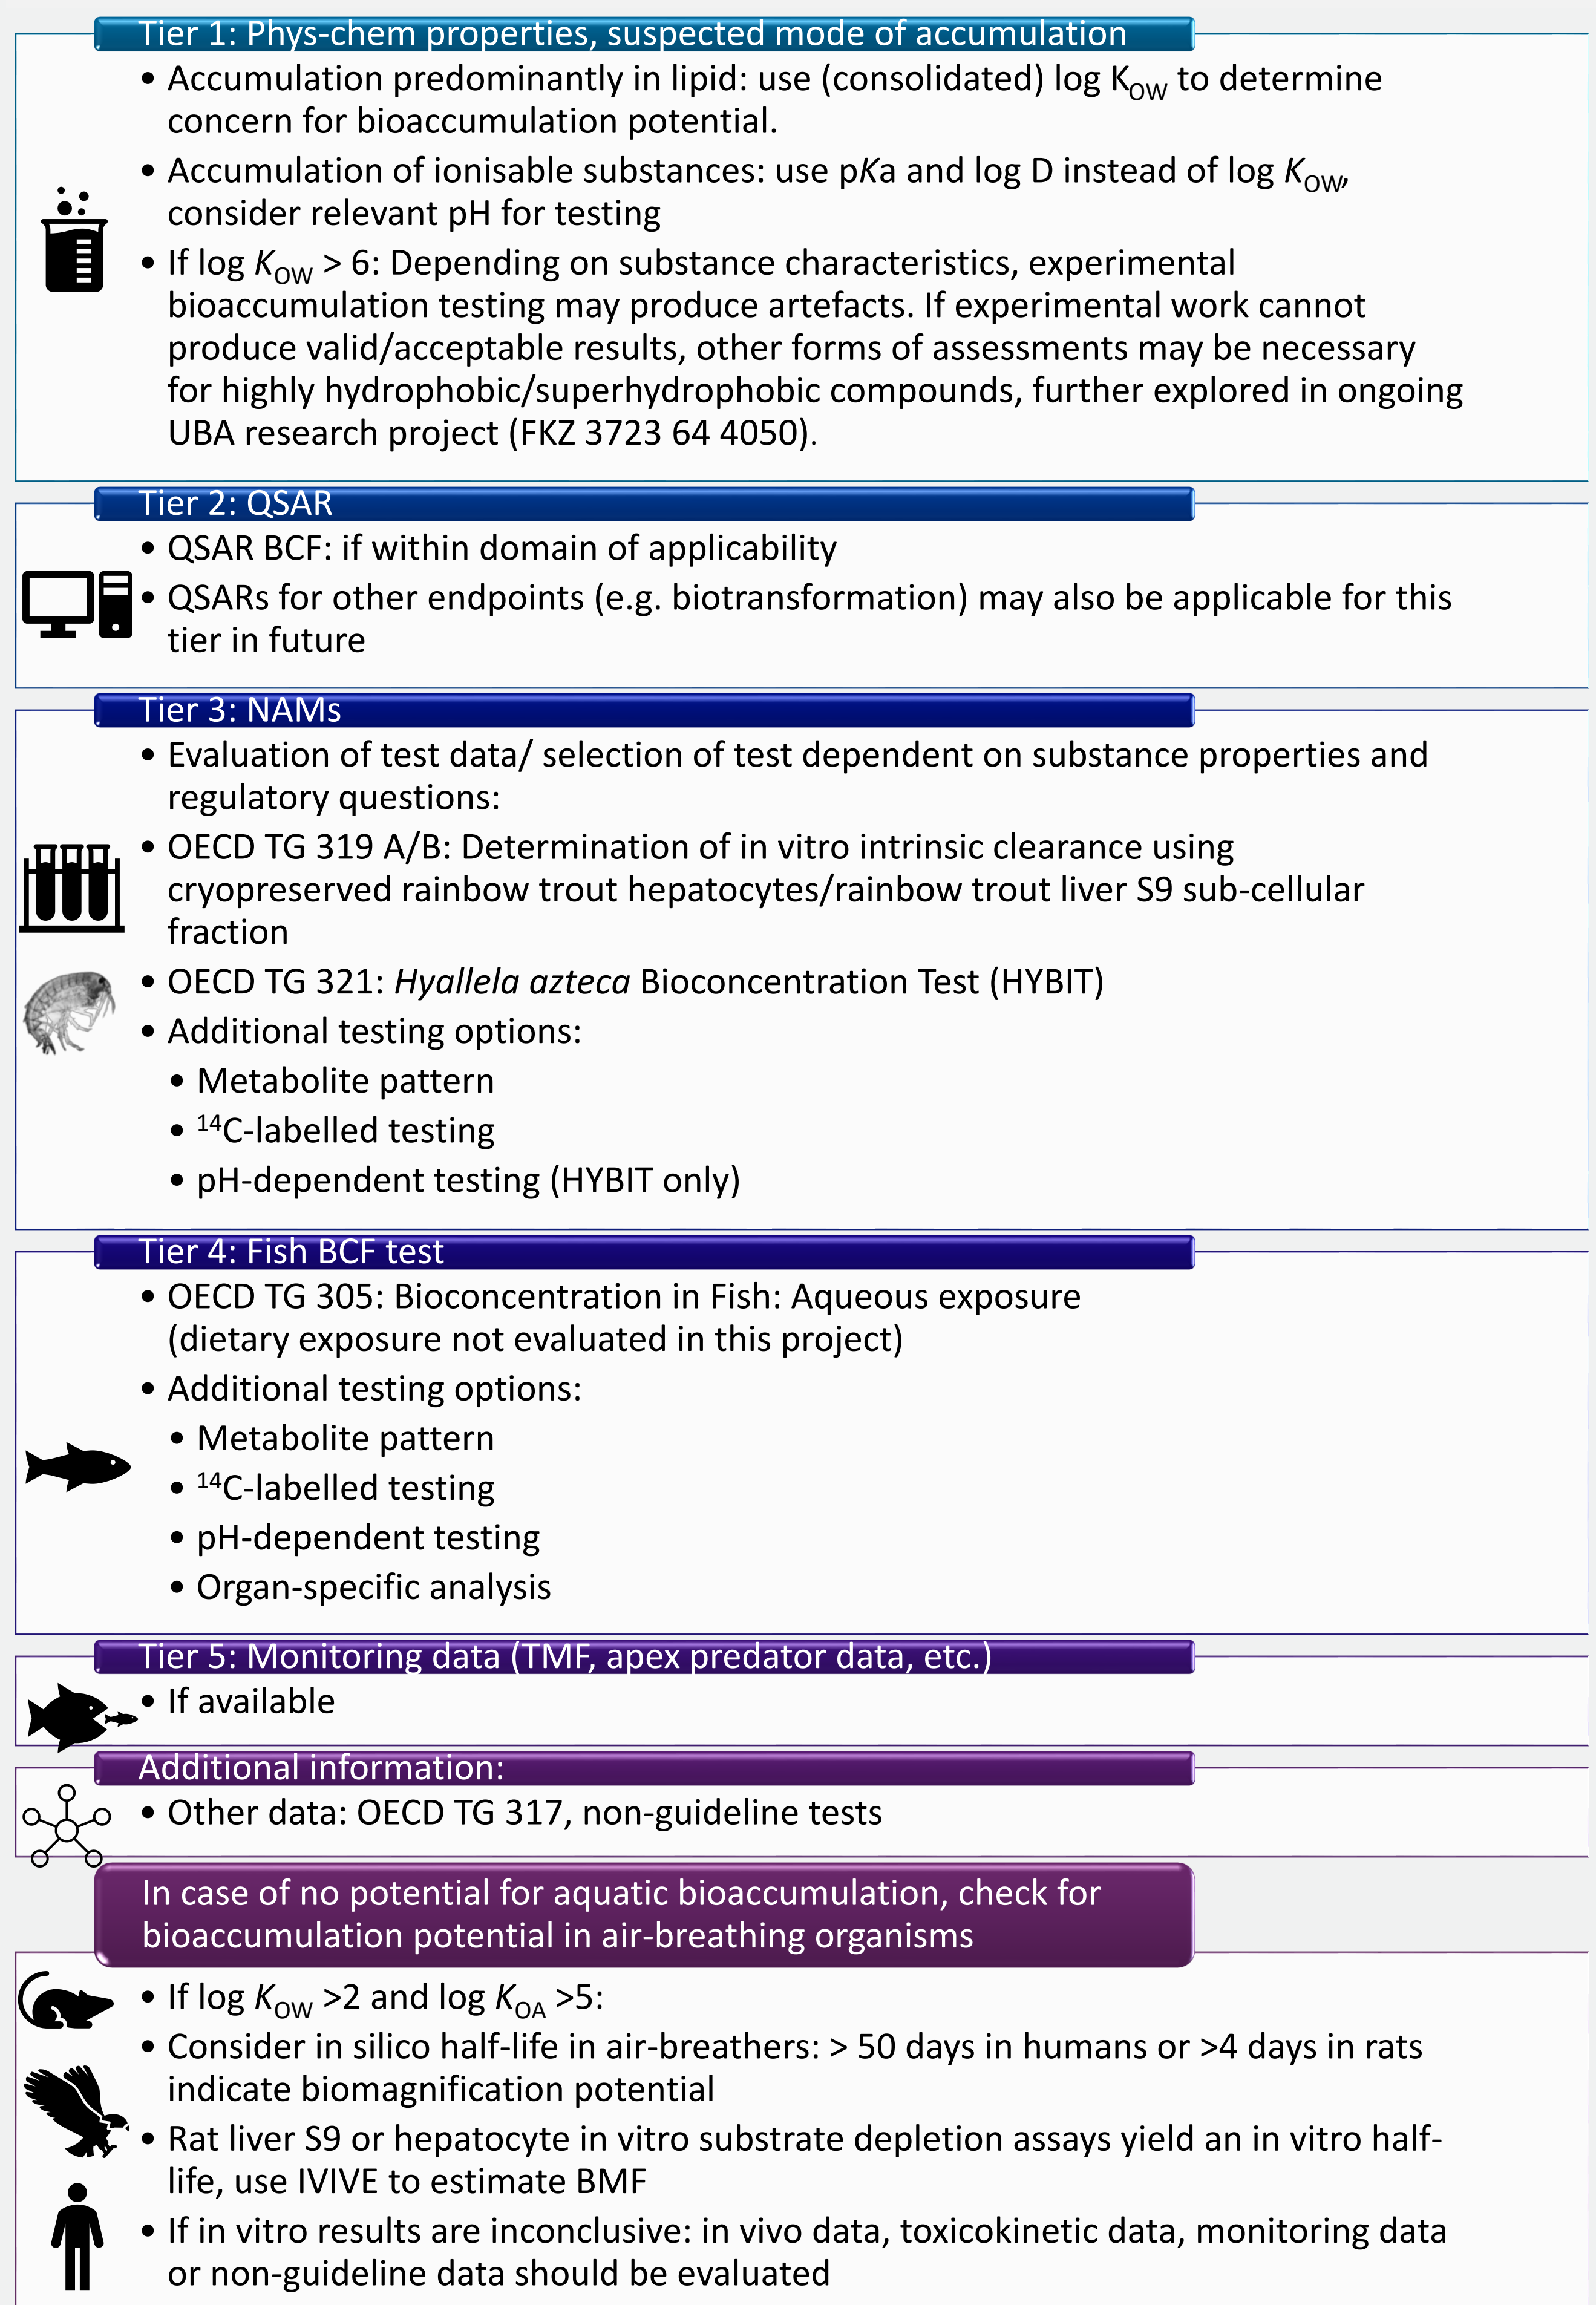

Figure 1: Proposal for an *Integrated Assessment Strategy for Aquatic and Terrestrial Bioaccumulation*

Evaluate against regulatory threshold of concern, if specified. Move to higher tier if data is not sufficiently conclusive for decision-making for bioaccumulation assessment or for secondary poisoning, as needed. Use all available data to inform decision-making.

**HYBIT (OECD TG 321):** Available HYBIT data reflect the results of data used for regulatory decisions. Metabolic differences of *H. azteca* to fish are visible for PAHs.

**Depletion assay (rat):** It was demonstrated that for air-breathing organisms, in vitro biotransformation data from rat hepatocytes or S9 fractions can be generated in analogy to OECD TG 319 A/B. Refinement and validation of the rat assays are necessary.

## Current limitations:

Difficult substances like superhydrophobic chemicals, ionisables and surfactants require extra care in evaluation to avoid misinterpretation of test data → Applicability domain!

## Way forward:

For the rat in vitro tests, the estimation of a BMF through IVIVE models needs further development. Also, an agreed OECD test guideline for air-breathing organisms (rodents and possibly bird and human cell lines) would be helpful for regulatory application.

NAMs for regulatory bioaccumulation assessment are ready to be integrated into the different substance regulations, also beyond REACH, to reduce reliance on animal testing while maintaining the same level of protection as current EU regulatory approaches.
